

Lecture 7: Probability

Chapter 2.x

1 / 19

Outcomes

Probability forms the theoretical backbone of statistics. We use probability to characterize randomness.

We often frame probability in terms of a **random process** giving rise to an **outcome**.

Typical examples

- ▶ Die roll: 6 outcomes
- ▶ Coin Flip: 2 outcomes

2 / 19

Disjoint AKA Mutually Exclusive Outcomes

Two outcomes are **disjoint (AKA mutually exclusive)** if they cannot both occur at the same time.

Die example:

- ▶ Rolling a 1 and a 2 are disjoint.
- ▶ Rolling a 1 and rolling “an odd number” are not disjoint.

3 / 19

Addition Rule of Probability

If A_1 and A_2 are disjoint outcomes, then

$$P(A_1 \text{ or } A_2) = P(A_1) + P(A_2)$$

Ex: Rolling 1 and 2 are disjoint, so:

$$P(\text{rolling 1 or 2}) = P(\text{rolling 1}) + P(\text{rolling 2}) = \frac{1}{6} + \frac{1}{6}$$

4 / 19

General Addition Rule of Probability

If A_1 and A_2 are two outcomes (not necessarily disjoint), then

$$P(A_1 \text{ or } A_2) = P(A_1) + P(A_2) - P(A_1 \text{ and } A_2)$$

Venn diagram:

General Addition Rule of Probability

Events are just combinations of outcomes. Ex: Deck of cards

- ▶ A_1 = event we draw a diamond
- ▶ A_2 = event we draw a face card

These two events are not disjoint, as there are 3 diamond face cards. Venn diagram:

General Addition Rule of Probability

$$\begin{aligned}P(A_1 \text{ or } A_2) &= P(\text{diamond or a face card}) \\&= P(\text{diamond}) + P(\text{face card}) - \\&\quad P(\text{diamond AND face card}) \\&= \frac{13}{52} + \frac{3 \times 4}{52} - \frac{3}{52} = \frac{22}{52} = 42.3\%\end{aligned}$$

7 / 19

Sample Space and the Complement of Events

A die has 6 possible outcomes. The **sample space** is the set of all possible outcomes $S = \{1, 2, \dots, 6\}$.

Say event A is the event of rolling an even number i.e $A = \{2, 4, 6\}$. The **complement of event** A is $A^c = \{1, 3, 5\}$ i.e. getting an odd number.

Thm

$$P(A) + P(A^c) = 1$$

8 / 19

Independence

Two processes are **independent** if knowing the outcome of one provides no useful information about the outcome of the other. Otherwise they are dependent.

Consider:

1. Die rolls
2. You get a movie recommendation from your friend Robin, but then their significant other Sam also recommends it.
3. You compare test scores from two Grade 9 students in the same class. Then same school. Then same school district. Then same city. Then same state.

9 / 19

Independence

We say that events A and B are **independent** if

$$P(A \text{ and } B) = P(A) \times P(B)$$

Ex: Dice rolls are independent:

$$\begin{aligned} P(\text{rolling 1 and then 6}) &= P(\text{rolling 1}) \times P(\text{rolling 6}) \\ &= \frac{1}{6} \times \frac{1}{6} = \frac{1}{36} \end{aligned}$$

10 / 19

Conditional Probability

The conditional probability of an event A given the event B , is defined by

$$P(A|B) = \frac{P(A \text{ and } B)}{P(B)}$$

11 / 19

Example

Let's suppose I take a random sample of 100 Reed students to study their smoking habits.

	Smoker	Not Smoker	Total
Male	19	41	60
Female	12	28	40
Total	31	69	100

- What is the probability of a randomly selected male smoking?

$$P(S|M) = \frac{P(S \text{ and } M)}{P(M)} = \frac{19/100}{60/100} = \frac{19}{60}$$

- What is the probability that a randomly selected smoker is female?

$$P(F|S) = \frac{P(F \text{ and } S)}{P(S)} = \frac{12/100}{31/100} = \frac{12}{31}$$

12 / 19

Put It Together! Independence and Conditional Prob.

If A and B are independent events, then

$$P(A \text{ and } B) = P(A) \times P(B)$$

then

$$P(A|B) = \frac{P(A \text{ and } B)}{P(B)} = \frac{P(A) \times P(B)}{P(B)} = P(A)$$

i.e. $P(A|B) = P(A)$: the event B occurring has no bearing on the probability of A

13 / 19

Gambler's Fallacy: Roulette

You can bet on individual numbers, sets of numbers, or red vs black. Let's assume no 0 or 00, so that $P(\text{red}) = P(\text{black}) = \frac{1}{2}$.

14 / 19

Gambler's Fallacy: Roulette

One of the biggest cons in casinos: **spin history boards**.

Let's ignore the numbers and just focus on what color occurred.

Note: the white values on the left are **black** spins.

15 / 19

Gambler's Fallacy: Roulette

Let's say you look at the board and see that the last 4 spins were **red**.

You will always hear people say "Black is due!"

Ex. on the 5th spin people think:

$$P(\text{black}_5 \mid \text{red}_1 \text{ and } \text{red}_2 \text{ and } \text{red}_3 \text{ and } \text{red}_4) >$$

$$P(\text{red}_5 \mid \text{red}_1 \text{ and } \text{red}_2 \text{ and } \text{red}_3 \text{ and } \text{red}_4)$$

16 / 19

Gambler's Fallacy: Roulette

But assuming the wheel is not rigged, spins are independent i.e.
 $P(A|B) = P(A)$. So:

$$P(\text{black}_5 | \text{red}_1 \text{ and } \text{red}_2 \text{ and } \text{red}_3 \text{ and } \text{red}_4) = P(\text{black}_5) = \frac{1}{2}$$
$$P(\text{red}_5 | \text{red}_1 \text{ and } \text{red}_2 \text{ and } \text{red}_3 \text{ and } \text{red}_4) = P(\text{red}_5) = \frac{1}{2}$$

17 / 19

Next Week's Lab

Basketball players who make several baskets in succession are described as having a "hot hand." This refutes the assumption that each shot is **independent** of the next.

We are going to investigate this claim with data from a particular basketball player: Kobe Bryant of the Los Angeles Lakers in the 2009 NBA finals.
