### Lecture 14: Hypothesis Testing Part I

Chapter 4.3

# Goals for Today

- Introduce Hypothesis Testing Framework
- Testing Hypotheses Using Confidence Intervals
- Types of Errors
- ► Testing Hypotheses Using p-Values

# Statistical Hypothesis Testing

### Example

We flip a coin many times and start to suspect that it is biased:

#### Example

We flip a coin many times and start to suspect that it is biased:

- ▶  $H_0$ : the coin is fair. i.e. the probability of heads is p = 0.5
- ▶  $H_A$ : the coin is not fair. i.e.  $p \neq 0.5$

# Crucial Concept: Conclusions of Hypothesis Tests

In the criminal justice system, the jury's verdict does NOT make any statement about the defendant being innocent, rather that there was not enough evidence to prove beyond a reasonable doubt that they were guilty.

Let's compare criminal trials to hypothesis tests:

Let's compare criminal trials to hypothesis tests:

#### Truth:

- Truth about the defendant: innocent vs guilty
- ▶ Truth about the hypothesis:  $H_0$  or  $H_A$

Let's compare criminal trials to hypothesis tests:

#### Truth:

- Truth about the defendant: innocent vs guilty
- ▶ Truth about the hypothesis:  $H_0$  or  $H_A$

#### Decision:

- Verdict: not guilty vs guilty
- ► Test outcome: "Do not reject  $H_0$ " vs "Reject  $H_0$ "

#### Testing Hypotheses Using Confidence Intervals

Example on page 173: The average 10 mile run time for the Cherry Blossom Run in 2006  $\mu_{2006}$  was 93.29 min. Researchers suspect  $\mu_{2012}$  was different:

#### Testing Hypotheses Using Confidence Intervals

Example on page 173: The average 10 mile run time for the Cherry Blossom Run in 2006  $\mu_{2006}$  was 93.29 min. Researchers suspect  $\mu_{2012}$  was different:

- ▶  $H_0$ : average time was the same. i.e.  $\mu_{2012} = 93.29$
- ▶  $H_A$ : average time was different. i.e.  $\mu_{2012} \neq 93.29$

# Testing Hypotheses Using Confidence Intervals

#### **Decision Errors**

#### **Decision Errors**

- ▶ Trade-off between these two error rates
  - procedures with lower type I error rates typically have higher type II error rates
  - vice-versa

#### **Decision Errors**

- Trade-off between these two error rates
  - procedures with lower type I error rates typically have higher type II error rates
  - vice-versa
- ▶ In other words, there is almost never a procedure that makes no type I errors and no type II errors. Some sort of balance between the two is required

#### Next Time
